

Soil structure & health

Renew pasture

Sow

Healthy soils support sustainable, profitable plant growth. Soil structure and biology are key physical indicators of soil quality, and play a critical role in selecting appropriate pasture renewal methods.

The risks

Cultivation, particularly with PTO powered equipment (e.g. power harrowing), can degrade soil structure, disrupt biological activity, release soil N and release carbon. Fragile soils such as ash, pumice, light/sandy loams and some peats are particularly vulnerable to loss of structure, with long-term physical effects including compaction, pan formation, reduced porosity, erosion and run-off.

Earthworms and a friable soil structure are signs of soil health.

Soil quality & new pasture

Cultivation, particularly with PTO powered equipment (e.g. power harrowing), can degrade soil structure, disrupt biological activity, release soil N and release carbon. Fragile soils such as ash, pumice, light/sandy loams and some peats are particularly vulnerable to loss of structure, with long-term physical effects including compaction, pan formation, reduced porosity, erosion and run-off.

Do not disturb

Direct drilling or minimum tillage reduces soil disturbance and helps protect soil structure, especially on fragile or light soils. It also reduces the number of passes over the soil with heavy machinery; and minimises disruption to soil biological activity (e.g. beneficial insects, microbes). But more care, and usually cost, with insect and slug control is needed.

What's down there?

A visual soil assessment (VSA) helps identify soil quality issues and provide a practical, immediate insight into overall soil health. A VSA Field Guide can be downloaded from Landcare Research or videos are available on YouTube.
